Lead Editor

BMC Nursing

Dear Dr. Pranab,

Please find attached our manuscript entitled “**Associations between trust in traditional, social, and artificial intelligence-driven information sources and influenza vaccine decisions among nurses: A multi-centre study in three Asian populations**”, which we wish to submit for consideration as a **Research Article** in **BMC Nursing**.

This study addresses an important and timely issue in nursing and public health: how trust in traditional and emerging health information sources relates to influenza vaccination behaviour among nurses. Nurses play a critical role in protecting patients and maintaining health system resilience, yet influenza vaccination uptake remains variable across settings. In the context of a rapidly evolving health information environment shaped by social media and artificial intelligence (AI), understanding how trust in different information sources may relate to vaccination decisions has become increasingly relevant to nursing practice, workforce protection, and evidence-based health communication.

We conducted a multicentre cross-sectional online survey among nurses in **Brunei, Hong Kong, and Singapore** and analysed responses from **1,966 participants**. We examined influenza vaccination uptake, the **5C psychological antecedents of vaccination**, and trust in multiple sources of general health information, including government websites, family doctors, family and friends, social media, and AI chatbots. Using both **effect modification** and **mediation** frameworks, we explored how trust in these sources was associated with the psychological antecedents of vaccination and uptake decisions. Overall influenza vaccination uptake was **62.0%**, with marked variation across sites. We found that higher trust in AI chatbots attenuated the negative association between complacency and vaccine uptake, while trust in social media and AI chatbots showed small indirect associations with lower uptake through higher calculation.

We believe this manuscript is well suited to **BMC Nursing** because it addresses **evidence-based nursing care, nursing service delivery**, and the broader nursing workforce context in which information environments may influence preventive health behaviours. The study also provides cross-population evidence from Asian settings and offers insights relevant to communication strategies, digital health engagement, and vaccination promotion among nurses. These themes align well with the journal's interest in nursing practice, service delivery, and scientifically valid research with implications for nursing policy and care.

This manuscript is original, has not been published previously, and is not under consideration for publication elsewhere. All authors have read and approved the final version of the manuscript and agree to its submission to **BMC Nursing**. Ethical approval was obtained from the relevant institutional review boards in Hong Kong and Brunei Darussalam, and the study protocol in Singapore was reviewed and determined not to require formal ethical approval according to local procedures. No conflicts of interest are declared. Thank you for considering our manuscript for publication in **BMC Nursing**. We believe our findings will be of interest to readers concerned with nursing practice, vaccination behaviour, digital health information, and workforce resilience. We look forward to your response.

Sincerely,

Dr. Kin On Kwok
